

Network rack heat dissipation function

Overview

Proper server rack cooling is essential to prevent overheating, improve performance, and extend equipment lifespan. Rack mount equipment generates heat as a result of the processes it completes; the amount of heat a piece of equipment dissipates is approximately equal to the total electrical power delivered to it. This heat is absorbed by the ambient air in the server, and removed by airflows generated by fans. Modern network racks face new physical constraints: deeper switches, hotter PoE++ loads, and thicker Cat6A cabling. Heat dissipation is governed by the Laws of Thermodynamics. This unit describes the amount of heat required to heat a British pound of water by 1 degree Fahrenheit. Learn about cooling efficiency and solutions.
